Pushing the HDFI axis one link down in REAL human SAH-CSF: heme-handling protein -> neuronal-injury protein
PXD030593 (label-free DDA, SAH n=4 vs control n=4, per-sample total-intensity normalised)

Honest scope: n=4v4 -> every rho is an 8-point exploratory association, NOT a tested mediation; HMOX1/GPX4 remain below CSF detection so the full HDFI_protein is still NOT computable (uses detectable members only).
Blood-contamination controls (HBA1/HBB/ALB/TTR) are reported, not hidden -- one SAH sample is Hb-high (possible contamination) and one is injury-high; the direction is corroborated VERBATIM by the larger independent cohort PMC11267790 (SAH n=23 vs control n=10).
